On behalf of the Fermi LAT  
collaboration

# AGN & blazar characteristics

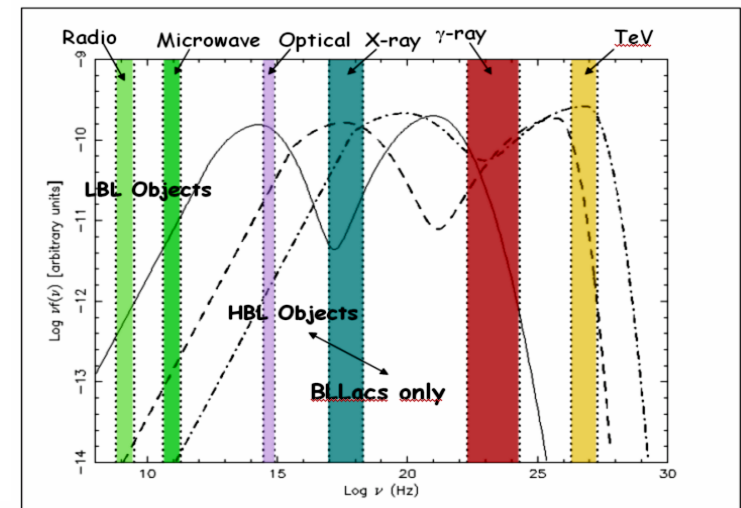

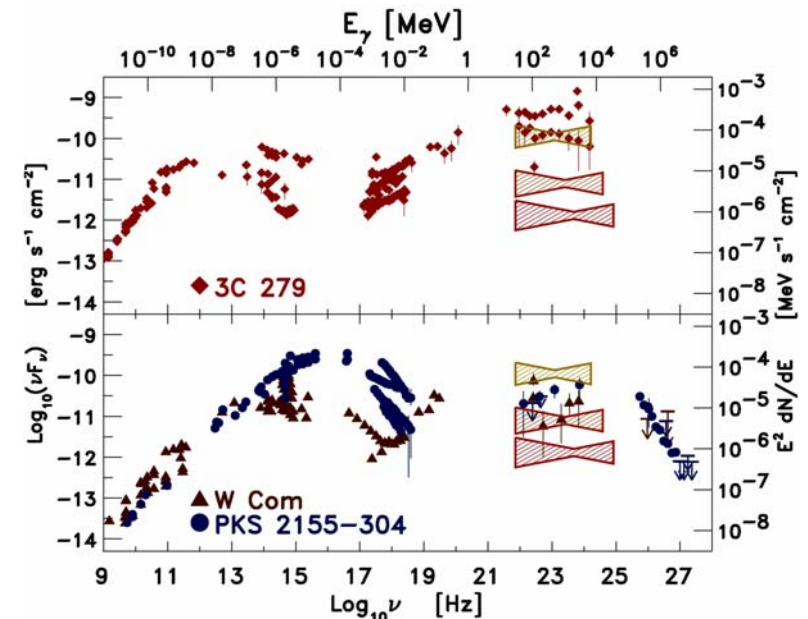

Almost all galaxies contain a massive black hole

- ★ 99% of them are (almost) silent (e.g. our Galaxy)
- ★ 1% is active (mostly radio-quiet AGNs): accretion onto a central, supermassive black hole. Accretion disks produce optical/UV/X-ray emission via various thermal processes
- ★ 0.1% is radio loud: jets mostly visible in the radio
- ★ Jets: highly collimated relativistic outflows with Lorentz factor about 10

- ✓ Compact radio core, flat or inverted spectrum, relatively high radio and optical polarization
- ✓ Extreme variability at all frequencies (gamma-rays too), large brightness temps, superluminal motion
- ✓ Unified Model: observer line-of-sight determines source properties, e.g., radio galaxy vs blazar
- ✓ Other factors: accretion rate, BH mass and spin, host galaxy
- ✓ **FSRQs**: bright broad emission lines, sometimes a “blue bump” (accretion disc), multi-temperature disk emission, broad lines in OUV, non-thermal components peak in IR & hard X-ray/MeV regime, high luminosity ( $L \sim 10^{48} \text{ erg s}^{-1}$ ) and  $z \geq 1$
- ✓ **BL Lacs**: weak ( $EW < 5 \text{ \AA}$ ) emission lines, little or no evidence of disk or emission lines in Opt-UV, non-thermal peaks in UV/soft X-rays & GeV, lower luminosity ( $L \sim 10^{45} \text{ erg s}^{-1}$ ) and  $z < 0.5$

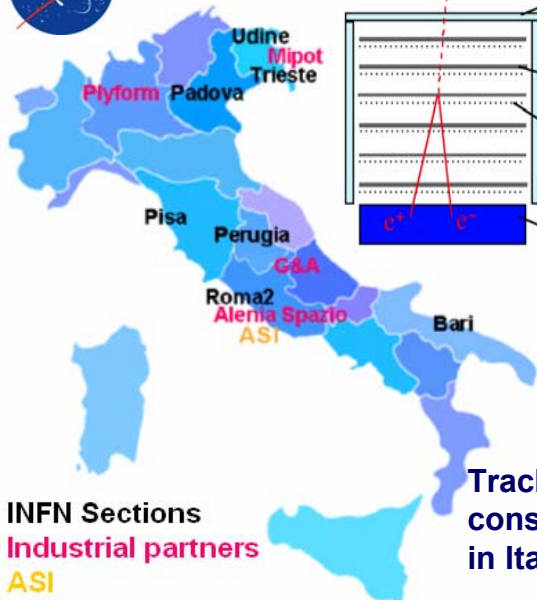

# Key question for blazars

- ❑ Emission mechanisms (especially for high energy component)
  - ❑ Leptonic (IC of synchrotron or external photons) vs hadronic ( $\pi_0 \rightarrow \gamma\gamma$ , proton synchrotron)
- ❑ Emission location
  - ❑ Single zone for all wavebands (completely constraining for simplest leptonic models)
  - ❑ Opacity effects and energy-dependent photospheres
- ❑ Particle acceleration mechanisms
  - ❑ Shocks, Blandford-Znajek
- ❑ Jet composition
  - ❑ Poynting flux, leptonic, ions
- ❑ Jet confinement
  - ❑ External pressure, magnetic stresses
- ❑ Accretion disk—black hole—jet connection
- ❑ Blazars as probes of the extragalactic background light (EBL)
- ❑ Effect of blazar emission on host galaxies and galaxy clusters

## The Large Area Telescope (LAT)

[fgst.slac.stanford.edu](http://fgst.slac.stanford.edu)  
PI: P. Michelson (Stanford Univ.)

- Launched 11 June 2008
- 2.4 sr FOV
- First year survey mod operation:  $\pm 35^\circ$  rocking about orbital plane each orbit  $\Rightarrow$  full sky coverage every 3 hours
- Energy range: 20 MeV to  $>300$  GeV,  $\Delta E/E \approx 10-15\%$

**Gamma Ray Burst Monitor (GBM):**  
correlative transient observations  
 $\sim 8$  keV – 30 MeV

**Large Area Telescope (LAT):**  
 $\sim 20$  MeV  $\rightarrow$  300 GeV

<http://fermi.gsfc.nasa.gov>

# 3 month photon counts map

## 3 month high confidence source list

- 205 sources with significance  $> 10\sigma$  (EGRET found fewer than 30).  
Typical 95% CL error radius is  $< 10$  arcmin.

## Variable sources in the LAT Bright Source List

- Based on 1 week time scales
- 68/205 show variability with probability > 99%
- Isotropic distribution  $\Rightarrow$  blazars

# AGN/blazar associations

## Fermi-GST LAT bright source list catalog, 0FGL:

132 sources with  $TS > 100$ ,  $|b| > 10^\circ$  7 pulsars, **125 AGN candidates**

### CGRaBS (Healey et al. 08)

1627 radio sources from CRATES  
association based on Figure-of-Merit (spatial,  
radio and X spectrum) established from EGRET

101 high-conf. ( $P > 90\%$ ) associations  
14 low-conf. ( $40\% < P < 90\%$ ) associations

### BZCat (Massaro et al. 08)

Compilation of 2500 known blazars  
association based on spatial coincidence  
(Mattox et al., 01)

102 high-conf. ( $P > 90\%$ ) associations  
4 low-conf. ( $40\% < P < 90\%$ ) associations

## 3-month Survey: 205 LAT Bright Sources (LBS)

(Abdo et al. 2009, arXiv:0902.1340)

- o 205 sources with significance  $> 10\sigma$  (EGRET found fewer than 30).
- o Typical 95% CL error radius is  $< 10$  arcmin.  $\sim 1/3$  show variability.

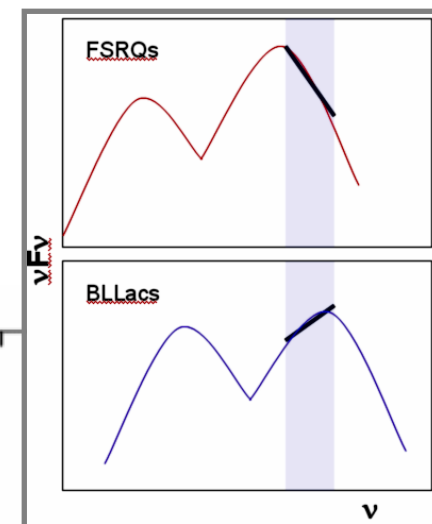

# Blazar population properties

- Aug/Sep/Oct high confidence list: 205 sources with  $>10\sigma$  detection
- 132 with  $|b| > 10^\circ$  (7 pulsars, 14 unid)
  - 111/125 are bright, flat spectrum radio sources
  - 98/111 have optical classifications, 89/111 have redshifts
  - CRATES (all-sky radio catalog), CGRaBS (all-sky optical spectra)

# Blazar population properties

- 34% BL Lac fraction (vs 19% for EGRET)

# Blazar population properties

Photon index vs flux

Luminosity vs redshift

# Luminosity functions

- **FSRQs**
  - Strong evolution
  - The 3 month LAT AGN sample measures the bright end of the luminosity distribution.
  
- **BL Lac objects**
  - No evidence of evolution
  
- **Combined emission from individual blazars in 3 month sample corresponds to 7% of EGRET extragalactic diffuse**

## Publicly LAT monitored source list

(?) Awaiting definitive detection by LAT.

# LAT source monitoring activities

- Automated Science Processing (ASP)
  - Transient detection: Uses source detection (pgwave) to find all point sources in data from each epoch (6hr, day, week)
  - Follow-up monitoring: Runs full likelihood analysis on list from source detection step + “Data Release Plan” (DRP) sources
  - $2 \times 10^{-6}$  ph cm<sup>-2</sup> s<sup>-1</sup> threshold (daily) for public release of non-DRP
- Flare Advocates:
  - LAT scientists from Galactic and Extragalactic groups examine output from ASP pipeline and perform follow-up analyses, produce ATels, and propose ToOs

# Fermi results for individual AGNs

## Fast flaring blazars: PKS 1454-354 and PKS 1502+106

- ❑ **PKS 1454-354**: factor  $\sim 5$  increase of  $>100$  MeV flux in 12 hours; achromatic flux variations
- ❑  $\Rightarrow$  weak radiative cooling regime, GeV variability driven by seed photon changes (cf. PKS 2155–304)

- ❑ **PKS 1502+106**:  $z=1.839$ , factor 3 increase in  $<12$  hrs, highest  $\Delta L/\Delta t$  in GeV band. Relevant variability and multifrequency campaign developed (see the dedicated poster).

# Fermi-LAT detection of NGC 1275 (Per A, 3C 84)

- NGC 1275: Classic example of a “cooling core” cluster. Voids or “bubble” seen in the X-ray must be inflated by some central source of power, i.e., an AGN.
- Variable emission on month to year time scales  $\Rightarrow$  AGN. Cannot be dark matter or diffuse cluster emission.
- Inferred blazar luminosity,  $L_{\gamma} \sim 10^{44} - 10^{45}$  erg  $s^{-1}$ , is consistent with power needed to inflate the voids.
- SED fitted with single zone SSC model (solid curve) and spine-sheath model (dashed)

# LAT detection of PMN J0948+0022 (a narrow Line Seyfert 1) and very large outburst from 3C 454.3

## PMN J0948+0022

- Seyfert galaxies are not normally associated with blazar emission
- PMN J0948+0022 SED is similar to an FSRQ's, but at much lower luminosity.
- Seyfert galaxies have lower mass BHs ( $\sim 10^7 M_{\text{sun}}$ ) & NS1s have high accretion rates  $\Rightarrow$  Eddington ratio is a key determinant of SED characteristics.

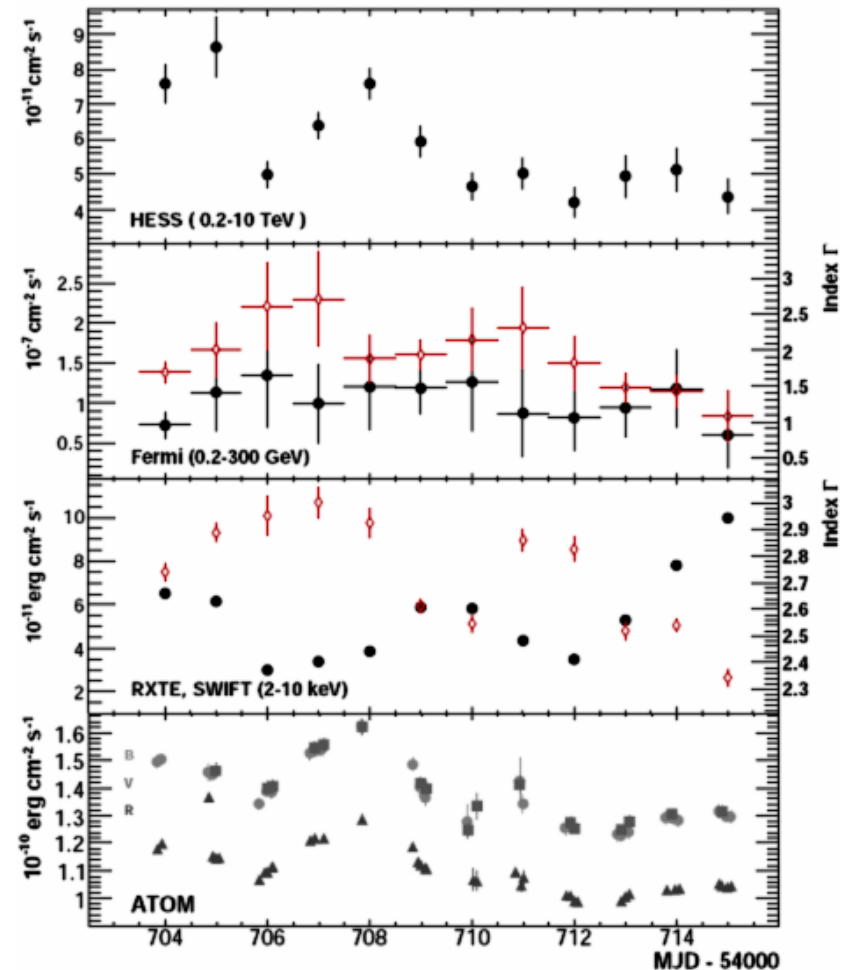

## 3C 454.3

- OVV quasar, very active since 2000; z = 0.859; VLBI, superluminal motion,  $\delta \sim 25$
- Brightest blazar during first few months of operations and variability time scales of < 3 days  $\Rightarrow \delta > 6$
- First definitive evidence of a spectral break in the GeV range:  $E_{\text{br}} = 2$  GeV,  $\Gamma_1 = 2.3$ ,  $\Gamma_2 = 3.5$
- $\Delta\Gamma = 1.2 > 0.5 \Rightarrow$  not from radiative cooling.
- This feature could either arise from “intrinsic” absorption, e.g., via  $\gamma\gamma$  opacity from accretion disk photons or it may represent a characteristic energy in the underlying particle distribution.

# PKS 2155-304: the Fermi-HESS MW campaign (Fermi, HESS, ATOM, RXTE (+ Swift))

- ❑ X-ray and VHE fluxes are **not** correlated, in contrast to July 2006 flare
- ❑ Lack of spectral variability in HESS band ( $\Delta\Gamma_{\text{VHE}} < 0.2$ )  $\rightarrow$  weak radiative cooling regime
- ❑ Significant spectral variability in X-rays ( $\Delta\Gamma_{\text{X}} \sim 0.5$ )  $\rightarrow$  strong cooling regime
  - ❑  $\Rightarrow$  Electrons producing the X-rays have higher energies than those producing the TeV.
- ❑ Optical and VHE fluxes are correlated
  - ❑ Optical is driving the TeV variability
- ❑ Lack of opt-GeV correlation
- ❑ X-ray flux and HE photon index are correlated
- ❑ **Multizone SSC models** are required.

# Conclusions

- ❑ The LAT is performing spectacularly well, both operationally and scientifically.
- ❑ Current set of results are just the tip of the iceberg.
- ❑ AGN/blazars field is among the main and fruitful science topic for the mission.
- ❑ Several Fermi multiwavelength campaigns on blazars have been completed and others are on-going
- ❑ The optimal high energy synergy between Fermi and Swift and between Fermi and TeV telescopes already demonstrated.
